

UNICITY · A SEED PROPOSAL FOR GREG KIDD

FAIR ACCESS HAS ALWAYS COME DOWN TO **THREE PROBLEMS.** THE THIRD IS STILL OPEN.

Cut out the middleman, prove who is on the other end, let the money move. The first two were solved a decade ago. The third is the hardest – a payment that settles between strangers, carries its own rule, and never lands on someone else's ledger.

That is the part Unicity builds.

The cryptography is done and open-source. We will be straight about what is still being built.

TALLINN · ZUG · ABU DHABI

FAIR ACCESS HAS ALWAYS COME DOWN TO THREE PROBLEMS.

→	CUT OUT THE MIDDLEMAN A decade of open infrastructure solved that.	SOLVED
→	LET VALUE MOVE FREELY Stablecoins now settle hundreds of billions a year between any two parties.	SOLVED
→	PROVE WHO IS ON THE OTHER END So the money itself knows who may receive it. The hardest of the three.	STILL OPEN

Two were solved a decade ago. The third is where the work is now.

IDENTITY REACHED THE RIGHT ARCHITECTURE BEFORE THE MARKET COULD CARRY IT.

GlobaliD had the architecture right early. The market couldn't carry it yet, and the mission moved into USBC.

The cryptography was solved a decade ago. The gap was structural – the credential lived beside the transaction, so nothing in the system ever required carrying it. A check that can be skipped without breaking the flow gets skipped.

The whole field stalled at the same place. Microsoft retired did:ion in 2023; Trinsic wound down before a credential was reused twice. Same wall, every time.

Every design put identity alongside the money, where traffic had a way around it.

USBC PUT IDENTITY **INSIDE THE DOLLAR** — THE CORRECT CONCLUSION.

A regulated tokenized deposit: identity carried in the money itself, settled under one OCC charter. The rule lives where the value lives, so there is nothing for traffic to route around.

One charter answers it at home. **Holding it between strangers, at machine speed, is the part still unbuilt.**

Inside a single charter it settles cleanly. The open question is what holds the same property across two charters — or between parties who share no trusted middle.

**MOST OF THE TRAFFIC ONLINE IS
ALREADY MACHINES – AND THEY HAVE
STARTED PAYING EACH OTHER.**

57.5%

OF WEB REQUESTS ARE
AUTOMATED, NOT HUMAN –
CLOUDFLARE, 2026, AND
CLIMBING

Machines have begun settling value directly – roughly **100 million payments on Base in nine months** (Chainalysis). Payments are messaging on steroids, and the messaging now runs at machine scale.

A machine cannot wait on hold while an intermediary clears it. It proves what it is in-band, and the payment settles in the same step.

| At machine speed, **the check has to travel with the money.**

A DOLLAR ON-CHAIN IS A ROW IN A LEDGER SOMEONE ELSE KEEPS.

Every move asks that ledger for permission first – the value lives in the database, not the hand that holds it. Unicity reduces it to a bearer file: the dollar carries its own value and moves directly between two parties, the way cash changes hands. The chain answers one question – has this been spent – and stays blind to the payment around it.

A TEN-DOLLAR NOTE SETTLES THE MOMENT IT CHANGES HANDS – **NOBODY SENDS IT TO A COMMITTEE.**

Cash carries its own proof: the recipient checks the note in hand and the transfer is final – no ledger to query, no clearer in the middle. A Unicity token moves the same way. The proof travels inside it, and the recipient verifies it on arrival, against the token alone.

Settlement happens at the point of receipt, with no third party in the path.

THE ONLY JOB A CHAIN EVER HAD: **HAS THIS BEEN SPENT?**

Global ordering, world state, smart-contract execution – every other job a blockchain took on was built on top of that one answer. Unicity keeps the answer and lets the rest go.

The oracle holds one thing: a proof that each token state is unique. It returns spent or unspent, and never sees the payment itself.

Three thin layers – consensus secures the base, the oracle holds the yes-or-no, holders transact client-side.

A chain with almost nothing left to do. **That is the design.**

CONSENSUS & EMISSION

decentralized base security

certified state root

UNIQUENESS ORACLE

stores only proofs that token states are unique

inclusion proofs

EXECUTION LAYER

agents and users transact client-side, off-chain

THE RULE LIVES INSIDE THE TOKEN.

Each token carries its own receive-condition – KYC, jurisdiction, sanctions status. A transfer completes only if the recipient satisfies the predicate the token carries. The check happens in the construction of the transfer itself: there is no issuer to call, and no monitor reading the flow after settlement. A transfer to a party that fails the predicate cannot be constructed. This is the piece GlobaliD lacked – identity that binds to the movement of value, instead of sitting to one side where traffic could pass it by.

Manage the risk inside the asset, and there is no flow left to catch afterward.

PRIVACY, COMPLIANCE, AND SPEED **PULL** **AGAINST EACH OTHER ON A SHARED** **LEDGER.**

Make the transactions private and the auditors go blind. Add the cryptography that lets them see again, and throughput collapses toward one payment a second.

The conflict is structural. As long as every party reads from and writes to the same ledger, two of the three hold at once – never all three.

Remove the shared ledger, and the three have nothing left to contend over.

Take away the thing they fight on, and **the trade-off has nowhere to live.**

THE HARD PART OF CASH-LIKE MONEY IS THE TRADE.

Holding a token that carries its own proof is the easy half. The trade is the hard half – two parties swapping value with no one in the middle to hold both legs. The standard fix is a hash-time-locked contract: a countdown, claim inside the window or the swap unwinds. The window is also the attack surface – one side stalls, runs the clock, and walks. That griefing problem has dogged atomic swaps for a decade. Unicity drops the clock: each side commits independently against the other's proof, and the swap forms for both at once, or never forms and each token stays exactly where it sat.

THE UNICITY TRUSTLESS ATOMIC SWAP

Both parties commit independently – the swap completes, or everyone keeps their token.

HASHED TIMELOCK (HTLC)

1 · A locks, reveals hash y

2 · B locks against same y

3 · A claims, revealing preimage x

4 · B must claim before timeout

THE TIMING TRAP

B late on step 4 – a dropped connection – and A keeps both.

UNICITY PREDICATE SWAP

WHEN TWO AGENTS SETTLE DIRECTLY, THE EXCHANGE IN THE MIDDLE HAS NOTHING LEFT TO DO.

At volume, trustless transfers compose into a market that coordinates itself – agents discover, negotiate, and settle peer to peer, each transfer carrying its own proof and its own receive-condition.

Agentic data is the first case to reach scale. A model buys a dataset, an attestation, a unit of compute – and the payment settles in the same step that proves what it is.

Settlement is the substrate the machine market runs on.

THE TEAM THAT BUILT THE SYSTEM ESTONIA'S E-GOVERNMENT RUNS ON.

KSI has secured Estonia's e-government records in production since 2012, eIDAS-grade.

The same KSI design held 300,000 transactions a second in Eesti Pank's 2021 digital-currency test – the lineage, not a live Unicity benchmark.

We will be straight about the state of it: the core is live and open-source, the repos are rough in places, and full credential support is still being built. We are protocol engineers, not lawyers.

THE WHITE PAPER IS MARKETING. THE WORK IS THREE MATH PAPERS.

We cringe at the white paper. The substance sits in three papers on GitHub – drop them into any model and it will check the proofs: privacy on both sides, and no double-spend. Throughput is a matter of sharding, by design; it was never claimed as a benchmark.

AGGREGATION

Off-chain and offline tokens; zero-knowledge proofs, no trusted setup.

github.com/unicitynetwork/aggr-layer-paper

EXECUTION

No double-spend; privacy held service-side and user-side; nothing waiting on a gatekeeper.

github.com/unicitynetwork/execution-model-tex

PREDICATES & SWAPS

The rule lives in the token; two strangers trade with no party between them.

github.com/unicitynetwork/unicity-predicates-tex

Public on GitHub, open to anyone who wants to read the proofs.

A CHARTER SETTLES CLEANLY **INSIDE ITS OWN WALLS.**

USBC reaches the right answer: identity inside the dollar, one OCC charter, a real deposit at a real bank. Within its own membership, it holds.

Across two charters, settlement still wants a trusted party in the middle – and a machine moving at machine speed has no human to clear it.

The settlement layer across charters, and across machines, is the one thing a charter cannot build for itself.

A PORTFOLIO SHAPED LIKE THIS ASSUMES ONE THING ALL THE WAY THROUGH: A PLACE TO SETTLE.

Identity, payments, exchanges, compute, tokenized money – five layers, 250 companies, each one resting on a place where a transfer becomes final with its rule still attached. That layer was assumed, not built.

IDENTITY WHO CAN ACT	GlobaliD · Indicio · Terminal 3
PAYMENTS HOW VALUE MOVES	Ripple · Square · Robinhood
EXCHANGES & CUSTODY WHERE VALUE IS HELD	Coinbase · Uphold
DATA · COMPUTE · SPEED WHAT IT RUNS ON	Filecoin · Solana · Brave
TOKENIZED MONEY MONEY WITH A RULE INSIDE	Vast Bank · USBC
WHERE IT SETTLES THE LAYER ASSUMED ALL THE WAY THROUGH	UNICITY – where a transfer becomes final with its rule still attached

PUT THE RULE WHERE THE MONEY IS, AND MAKE IT HOLD **BETWEEN STRANGERS.**

The first two of the three problems were solved a decade ago. The third – settlement that holds between two parties who share no bank and no trusted middle – is the part we built.

Raising **\$5M Seed** · \$25M cap / \$50M token FDV · SAFE + token warrant.

First build: a **USBC dollar** that settles the moment the credential checks out. The rule travels inside the money – who may receive it, under what jurisdiction – so a transfer that cannot satisfy it is never constructed. Identity inside the dollar, between any two parties, at machine speed.

A single charter settles at home. **This is the layer that carries the same rule between two banks, or two machines, that share nothing else.**
